

Tutorial sheet 3

Sol 1:- int linear-search(int *arr, int n, int key)
for $i = 0$ to $n-1$
if $arr[i] = key$
return i
return $n-1$

iterative insertion sort

void insertionSort(int arr[], int n)
int i, temp, j;
for $i = 1$ to n
temp $\leftarrow arr[i]$
 $j \leftarrow i-1$
while ($j \geq 0$ AND $arr[j] > temp$)
arr[j+1] $\leftarrow arr[j]$
 $j \leftarrow j-1$
arr[j+1] $\leftarrow temp$.

Recursive insertion sort

void insertionSort(int arr[], int n)
if ($n \leq 1$)
return
insertionSort(arr, $n-1$)
last = arr[n-1]
 $j = n-2$
while ($j \geq 0$ && $arr[j] > last$)
arr[j+1] = arr[j]
 $j--$
arr[j+1] = last.

Insertion Sort is called online sorting because it does not need to know anything about what values it will sort and the information is requested while the algorithm is running.

Sol 3 \Rightarrow (i) Selection Sort \Rightarrow .

time complexity = Best case $\propto O(n^2)$; worst case $\propto O(n^2)$

$O(n^2)$

S.C. = $O(1)$.

(ii) Insertion Sort \Rightarrow

time complexity = Best case = $O(n)$;

worst case = $O(n^2)$, Space complexity = $O(1)$

(iii) Merge sort = time complexity = Best case

= $O(n \log n)$, Worst case = $O(n \log n)$

Space complexity = $O(n)$.

(iv) Quick sort = time complexity = Best case = $O(n \log n)$, worst case = $O(n^2)$, S.C. = $O(n)$.

(v) Heap sort = time complexity = $O(n \log n)$, worst case = $O(n \log n)$, Space complexity = $O(1)$.

(vi) Bubble Sorting =

time complexity = Best case $O(n^3)$,

worst case = $O(n^2)$, space complexity = $O(1)$.

Sol 4 \Rightarrow Sorting	Inplace	Stable	Online
◦ Selection sort	✓	✓	
◦ Insertion sort	✓	✓	
◦ Merge sort			
◦ Quick sort	✓		
◦ Heap sort	✓	✓	
◦ Bubble sort			

Sol 5 \Rightarrow Iterative Binary Search :-

```
int binarysearch (int arr[], int l, int r,
int x)
```

```
{ while (l <= r) {
    int m = (l + r) / 2;
    if (arr[m] == x)
        return m;
    if (arr[m] < x)
        l = m + 1;
    else
        r = m - 1;
}
return -1;
}
```

Time complexity :-

- Best case = $O(1)$
- Average case = $O(\log_2 n)$
- Worst case = $O(\log n)$

Recursive Binary Search:-

int binarySearch (arr[], int l, int r,
int x)

```
{ if (r) = l) {  
    int mid ← (l+r)/2;  
    if (arr[mid] = x)  
        return mid;  
    else if (arr[mid] > x)  
        return binarySearch(arr,  
            l, mid-1, x);  
    else  
        return binarySearch(arr, mid+1,  
            r, x);  
}
```

}

- Best case.
- Time complexity = $O(1)$
 - Average case = $O(\log n)$
 - Worst case = $O(\log n)$

Sol 6 \Rightarrow Recurrence relation for binary recursive search

$$T(n) = T(n/2) + 1$$

Sol 7 $\Rightarrow A[i] + A[j] = k$

Sol 8 \Rightarrow Quicksort is the fastest general-purpose sort. In most practical situations, quicksort is the method of choice. If stability is important & space is

available, merge sort might be best.

Sol 9 Inversion count for any array indicates :
how far (or) the array is from being sorted).

If the array is already sorted, then the inversion count is 0, but if array is sorted in the reverse order, the inversion count is maximum.

arr[] = {7, 21, 31, 8, 10, 1, 20, 6, 4, 5}

```
#include <bits/stdc++.h>
```

```
using namespace std;
```

```
int mergeSort (int arr[], int temp[], int  
left, int right);
```

```
int merge (int arr[], int temp[], int  
left, int mid, int right);
```

```
int mergeSort (int arr[], int array-size)
```

```
{ int temp [array-size];
```

```
return mergeSort (arr, temp, 0, array-  
size - 1);
```

```
}
```

```
int mergeSort (int arr[], int temp[],  
int left, int right)
```

```
{ int mid, inv_count = 0;
```

```
if (right > left)
```

```
{ mid = (right + left) / 2;
```

```

    inv_count += -mergeSort(arr, temp, left, mid);
    inv_count += -mergeSort(arr, temp, mid+1, right);
    inv_count += merge(arr, left, mid+1, right);
}
return inv_count;

```

```

int merge (int arr[], int temp [], int left,
            int mid, int right) .

```

```

{ int i, j, k;
  int inv_count = 0;
  i = left;
  j = mid;
  k = left;

```

```

while ( (i <= mid-1) && (j <= right) )

```

```

{ if (arr[i] <= arr[j])
    temp[k++] = arr[i++];

```

```

else

```

```

{ temp[k++] = arr[j++];
  inv_count = inv_count +
    (mid - i);
}

```

```

}

```

```

while (i <= mid-1)
    temp[k++] = arr[i++];

```

```

while (j <= right)
    temp[k++] = arr[j++];

```

```

for (i = left; i <= right; i++)
    arr[i] = temp[i];
return inv_count;
}

```

```

int main()

```

```

{
    int arr[] = {7, 2, 31, 8, 10, 1, 20, 6, 4, 5};
    int n = size of arr / size of arr[0];
    int ans = mergeSort(arr, n);
    cout << "No. of inversion are " << ans;
    return 0;
}

```

Sol 10 → The worst case time complexity of quick sort is $O(n^2)$. The worst case occurs when the picked pivot is always an extreme (smallest or largest) element. This happens when input array is sorted or reverse sorted and either first or last element is picked as pivot.

→ The best case of quick sort is when we will select pivot as a mean element.

Sol 11 → Recurrence relation of:

(a) Merge sort $\Rightarrow T(n) = 2T(n/2) + n$;

(b) quick sort $\Rightarrow T(n) = 2T(n/2) + n$.

\Rightarrow Merge sort is more efficient & works faster than quick sort in case of larger array size or data sets.

→ Worst case complexity for quick sort is $O(n^2)$ whereas $O(n \log n)$ for merge sort.

Sol 12 ⇒ Stable selection sort

```
void stableSelectionSort (int a[], int n)
```

```
{ for (int i=0; i<n-1; i++)
```

```
{ int min = i;
```

```
  for (int j=i+1; j<n; j++)
```

```
    if (a[min] > a[j])
```

```
      min = j;
```

```
    int key = a[min];
```

```
    while (min > i)
```

```
    { a[min] = a[min-1];
```

```
      min--;
```

```
    }
```

```
    a[i] = key;
```

```
  }
```

```
}
```

```
int main()
```

```
{ int a[] = {4, 5, 3, 2, 4, 1};
```

```
  int n = size of (a) / size of a[];
```

```
  for (int i=0; i<n; i++)
```

```
    cout << a[i] << " ";
```

```
  cout << endl;
```

```
  return 0;
```

```
}
```

Sol 13 \Rightarrow The easiest way to do this is to use external sorting. We divide our source file into temporary files of size equal to the size of RAM & first sort these files.

- External Sorting: If the input data is such that it cannot be adjusted in the memory internally at once, it needs to be stored in a hard disk, floppy disk or any other storage device. This is called external sorting.
- Internal Sorting: If the input data is such that it can be adjusted in the main memory at once, it is called internal sorting.
